

Ocean Life Overview

The ocean is home to a vast variety of living organisms, from microscopic plankton to large whales.

Fish are one of the most common marine animals and come in many shapes, sizes, and colors.

Coral reefs are often called the 'rainforests of the sea' because they support a diverse ecosystem.

Marine mammals such as dolphins and whales breathe air but live in the ocean.

Plankton are tiny organisms that float in the water and form the base of the ocean food chain.

Oceans cover more than 70% of the Earth's surface and play a key role in regulating climate.
